I added a new cart page that allows the user to adjust the quantity and frequency of the item(s) and remove them from the cart. On the backend, I created a cookie class.

An issue that I still have is the layout for the number of items in the cart; I decided to just leave it next to the cart, but even though I tried (1) overlaying it on top of the cart and (2) aligning it with the cart to the left/right, they didn't work properly. A friend suggested that I could add js to the cart by making a counter for the quantity of the items, but I decided against it because I kept getting null references. If I do decide to use it, I will need to change the product detail and cart pages.

For my next steps, I expect to create more classes for different desserts and utilize them for adding to the cart and adjusting the js code so that they delete properly (currently hard-coded for the singular cookie item in the cart).
